Types of infections

- Common cold (mortality uncommon)
 - Rhinovirus. Spring, Summer, Early Fall
 - Coronavirus. Winter and early spring (3-4 species)
 - RSV and parainfluenza. Fall to Spring, or any.
 - Unidentified virus. 10-20%
- Seasonal influenza (mortality 0.1 to 0.2 %)
 - Various mutations of Influenza A or B virus. December to March
- Wuhan coronavirus (mortality 2% ?). December to ?
- SARS coronavirus (mortality 9.7%). November to July.

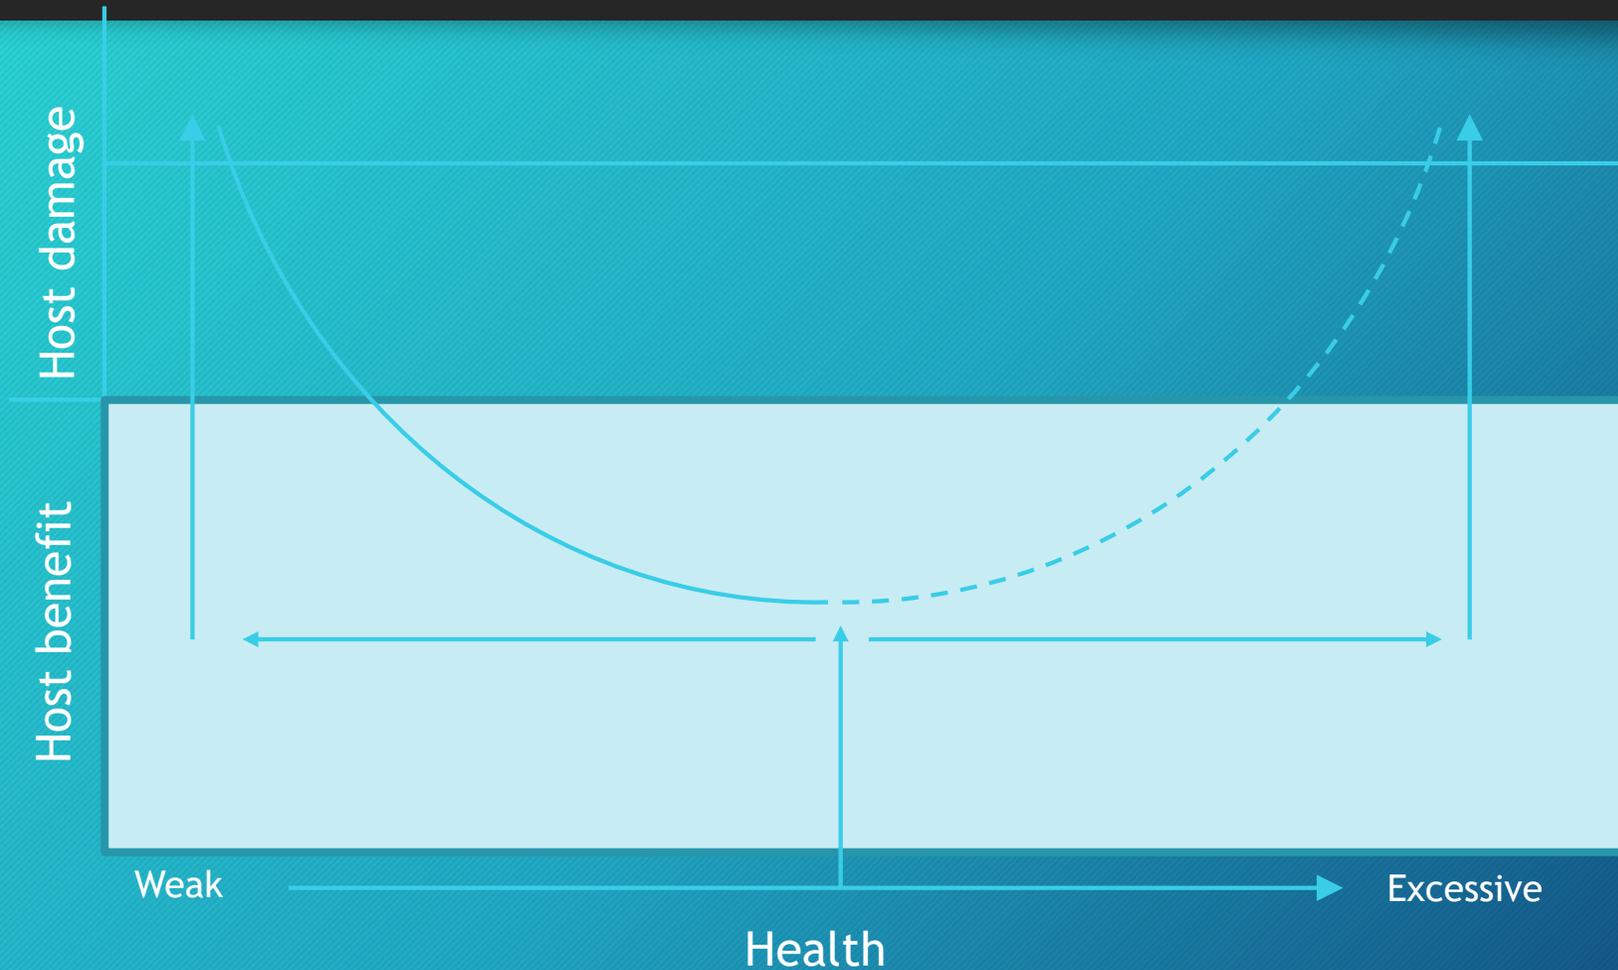

Possible host responses

- Acquire immunity with no visible symptoms
- Experience mild passing symptoms
- Experience normal symptoms but with mild expression.
- Experience normal symptoms with high fever and severe cough
- Complications of pneumonia, multi-organ involvement, cytokine storm
- Mortality

Infection

- A novel virus can infect a perfectly healthy individual.
- A perfectly healthy individual may have strong vital symptoms to infection.
- Infection in a healthy individual is less likely to lead to complications such as pneumonia.
- The most mortality in influenza and/or Wuhan coronavirus occurs in the elderly and those with pre-existing conditions or poor health.
- Certain deficiencies can result in an individual having a sub-optimal response to infection.
- Other deficiencies can result in an individual have an excessive inflammatory response to infection.

Damage-response model of infection

Pirofski LA, Casadevall A. The damage-response framework of microbial pathogenesis and infectious diseases. *Adv Exp Med Biol.* 2008;635:135-46.

Damage-Response in respiratory viral infection

Immune weakness

- Inefficient antibody response
- Inefficient cell-mediated response
- Complications of pneumonia or multi-organ involvement

Excessive response

- Excess inflammatory cytokines
- Massive systemic inflammation
- *Occurs in end-stage disease complications* such as pneumonia

Pathphysiology: Cytokines

- A beneficial anti-viral immune response common to all viral respiratory infections
- The following was observed in *mild influenza A infection* with seasonal virus
 - IL-6 and IFN- α had biphasic peaks on day 2 (17 x normal) and 5 (14 x normal)
 - TNF- α peaks on day 4 then rapidly drops off
 - IL peaks on day 4 (59x normal) lingering into day 6
 - Others may have unique periods

Cytokine storm

- Excessive cytokine response may occur in vitamin D deficiency, pneumonia, multi-organ infection, sepsis. It is a phenomenon of late-stage disease with pneumonia.
- It has been theorized that herbal immune stimulants may cause injury by enhancing cytokine storm in influenza. Specifically the use of Echinacea, Sambucus, and Astragalus have been questioned.
- Astragalus has a traditional contraindication in acute febrile illness unless it is specifically indicated by symptoms of chi deficiency according to the Chinese system.
- Research on Echinacea and Sambucus show a mix of effects on cytokines, stimulating some immune enhancing (inflammatory) ones and some anti-inflammatory. Clinically, this issue has not been reported in traditional use of these herbs.

Therapeutics and Prevention

- During season of prevalence.
- After suspected or known exposure
- After onset of symptoms
- Recovery period

Normalize host response during prevalence

- Optimize vitamin D levels - immunomodulating
- Optimize omega-3 fatty acids, including both EPA and DHA - immunomodulating
- Optimize activities and physical exercise that elevate body temperature - enhance immune response via heat shock proteins.
- Correct possible nutrient deficiencies that may depress immunity
- Avoid dietary influences which may depress immunity or aggravate inflammation.
- Correct sleep debt

Pathophysiology: Cholecalciferol

- Vitamin D essential for production of immuno-competence proteins in the immune cells of the respiratory tract (*discovery in 2004*)
- Vitamin D stimulates immuno-modulatory cytokines, putting a brake on cytokine “storm”
- Respiratory viral or bacterial infections are proposed as part of the profile of vitamin D deficiency syndrome.

The vitamin D winter

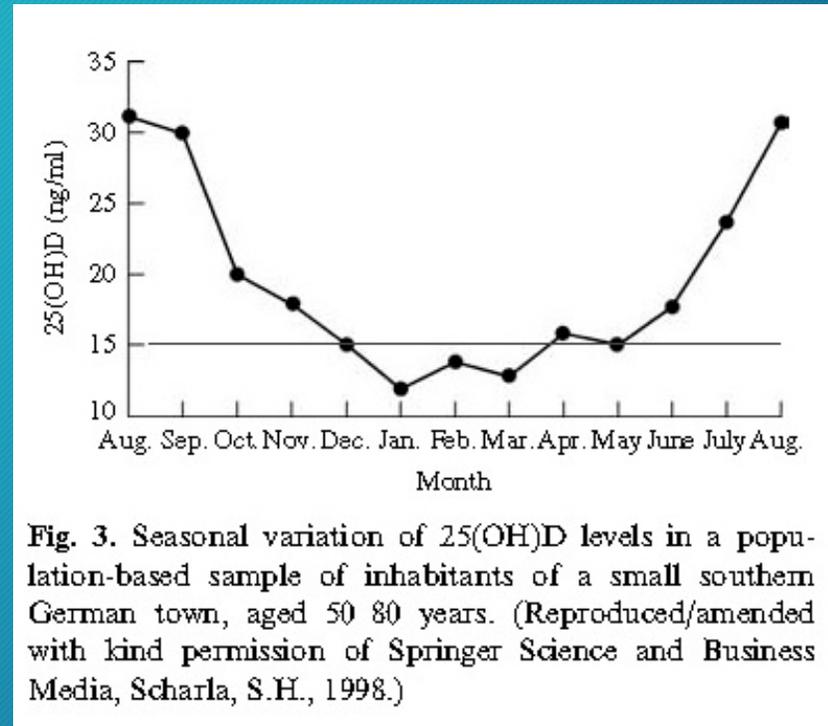

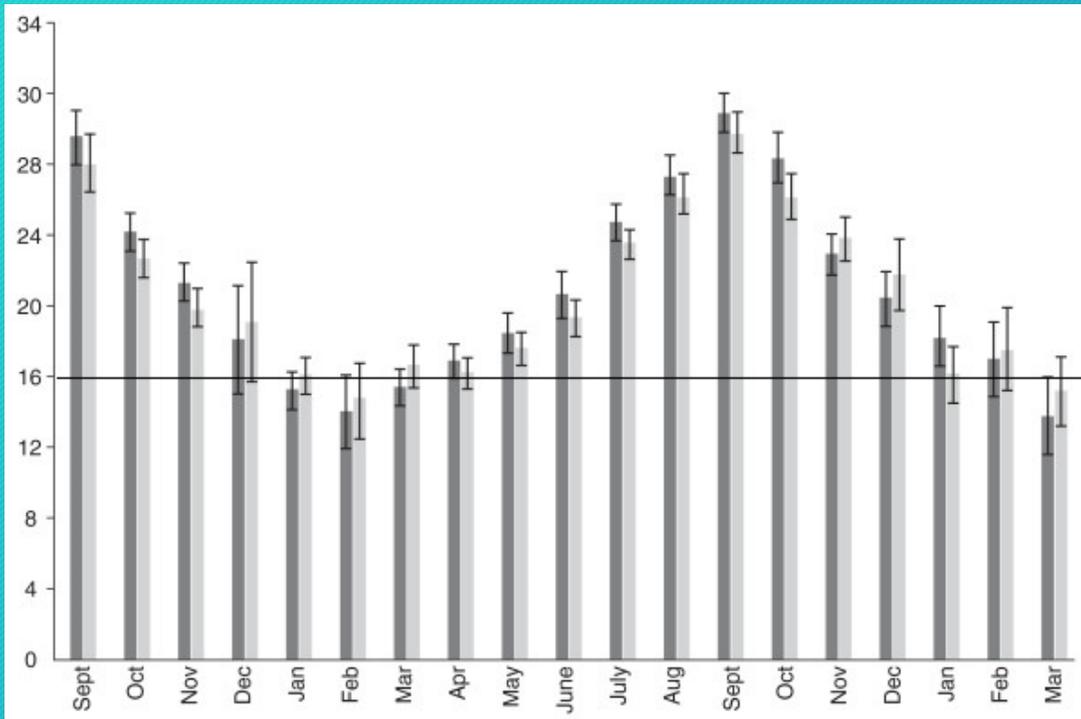

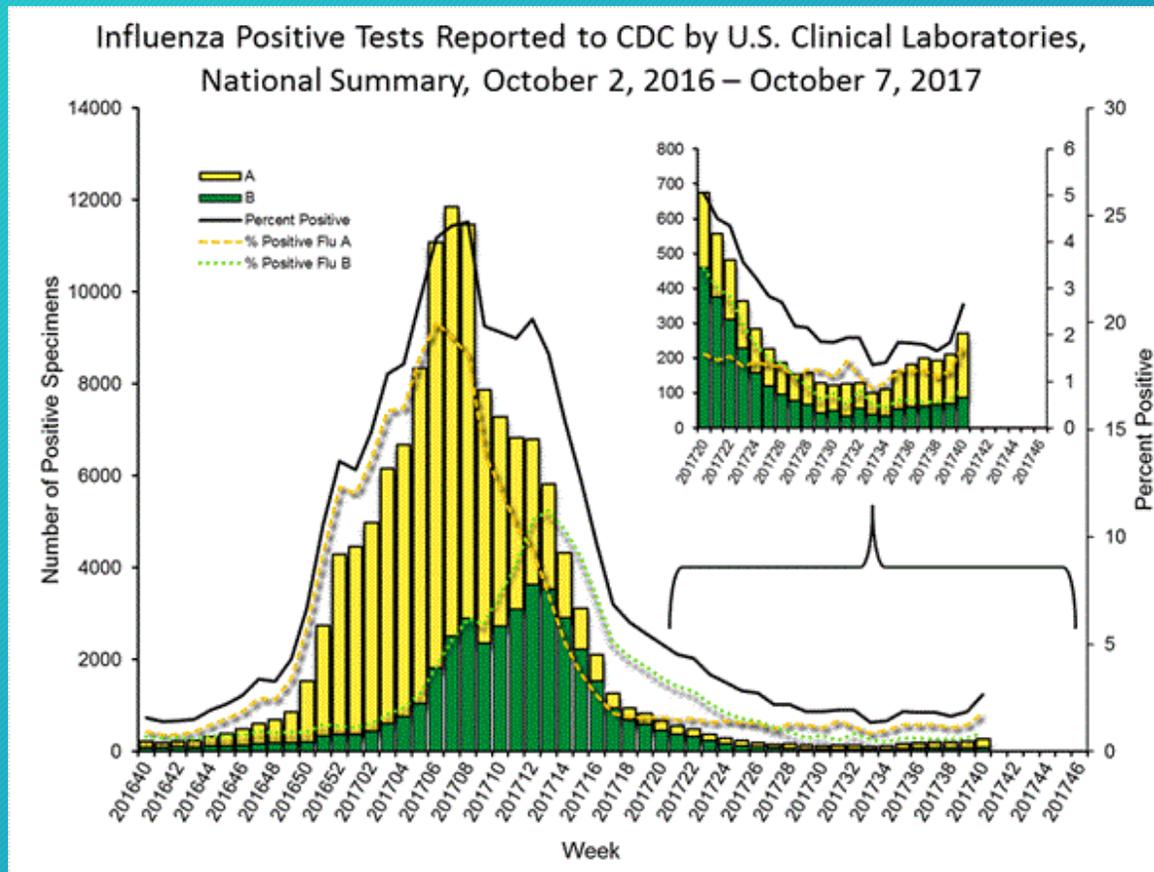

Fig. 3. Seasonal variation of 25(OH)D levels in a population-based sample of inhabitants of a small southern German town, aged 50-80 years. (Reproduced/amended with kind permission of Springer Science and Business Media, Scharla, S.H., 1998.)

Vitamin D levels in ng/mL in seasons in USA (left) and Germany (right). The black line is the level at which 1% of individuals develop Rickets or Osteomalacia, and at which *respiratory infections double*.

Seasonal Influenza follows Vitamin D

Vitamin D winter in China

- Seasonal influenza in China as here in North but later in the south
- 30% of males and almost 50% of females In Shanghai (middle latitude) had levels of frank deficiency, below 20 ng/mL

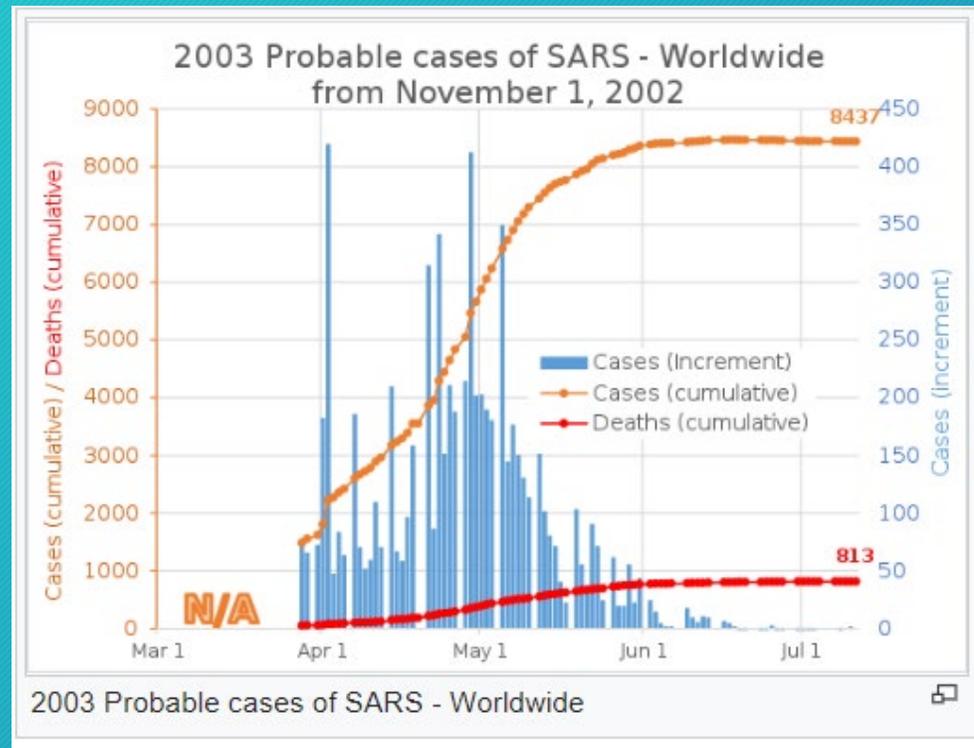

Sunlight in Northern China (Beijing) is lowest from November to February, and seasonal influenza is the same as for North America

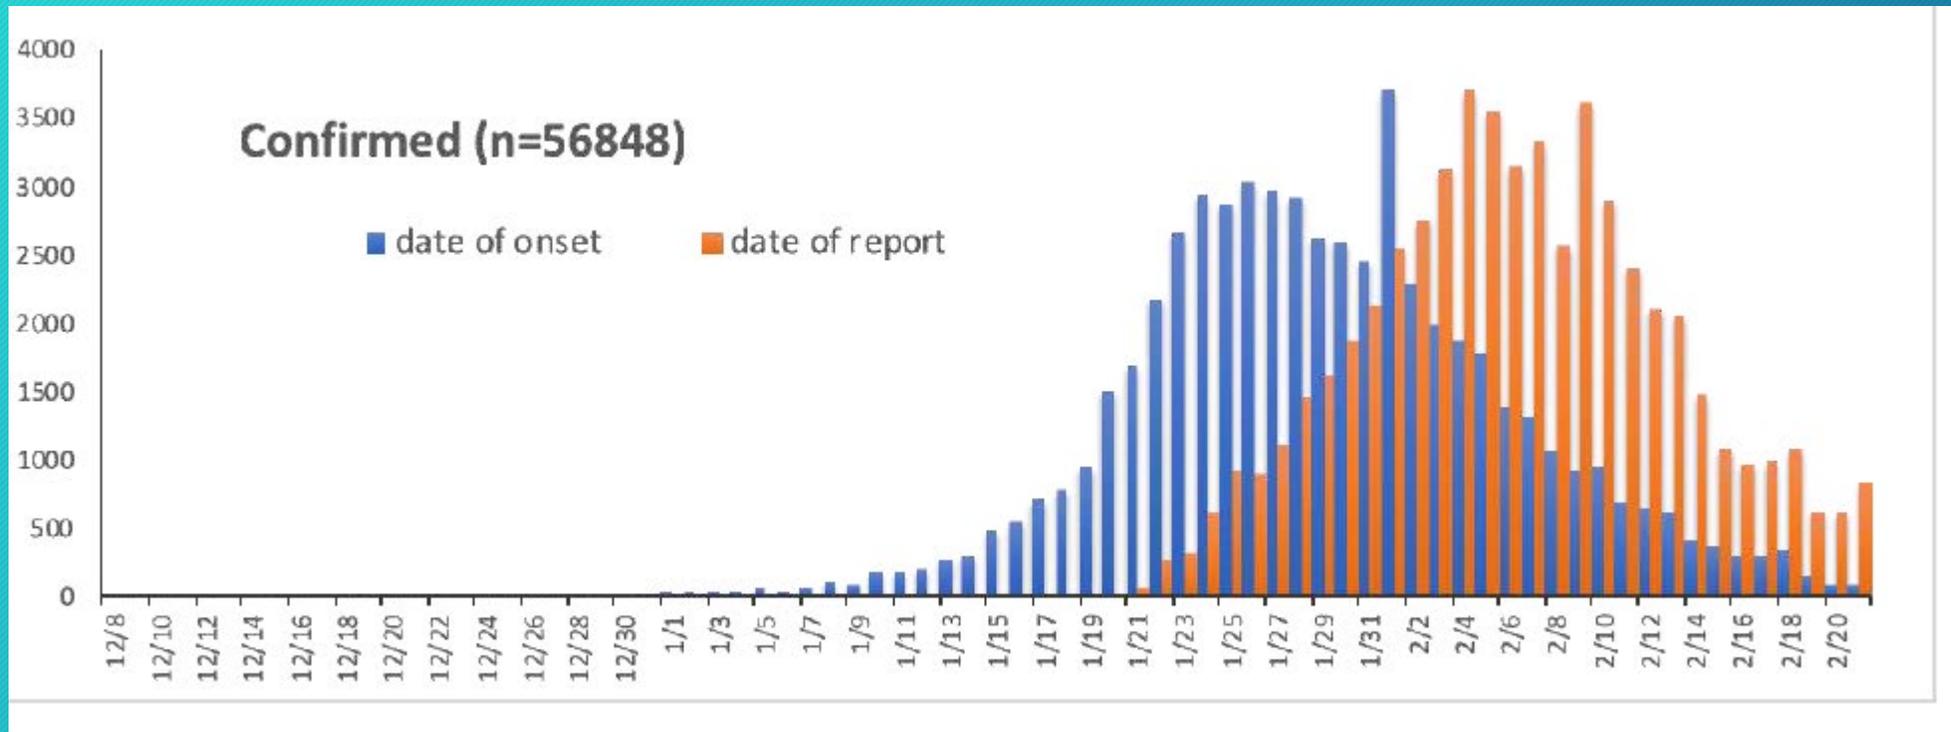

Sunlight in semi-tropical southern China is lowest from February through April, which matches seasonal influenza in there.

SARS in 2003 and vitamin D winter

SARS apparently first jumped hosts to humans in early November 2002. It then built to a peak corresponding to the vitamin D winter in southern China where the outbreak was most severe.

COVID-19 and vitamin D winter

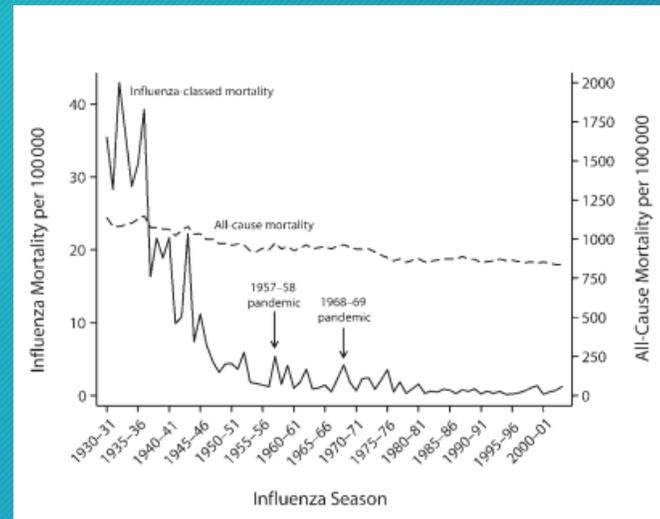

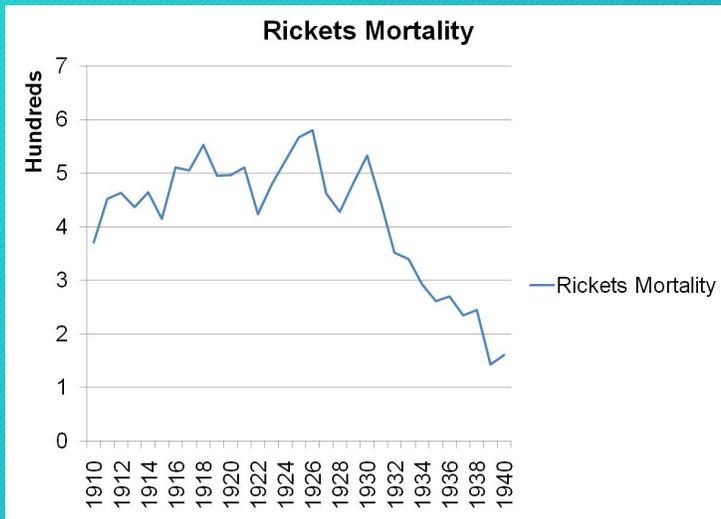

The COVID-19 virus is apparently following the same pattern

Vitamin D in the 1918 Flu pandemic

- Dawn to dusk factory conditions kept the average urban “healthy adult” out of the noon time sun continuously
- Ricketts was endemic in urban areas
 - 100% of a group of 250 bottle fed babies in New York
 - 100% of a group of babies in New Orleans by 1 y.o.
 - 95% of a group of 400 babies in Boston by age 8 months
 - 50% of a group of well-nourished breast fed infants in August developed Ricketts by March
- Nearly the entire population, and especially laboring adults, were subject to respiratory immunodeficiency and excessive inflammation from deficiency.

Mortality: Rickets vs Influenza

With the discovery of vitamin D and fortification of milk, both Rickets and Influenza mortality declined in parallel. The dramatic decline in influenza mortality indicates that the earlier mortality was due to factors other than virulence of the influenza.

Pathophysiology: Serum 25(OH)D3

- 150 ng/mL No toxicity at twice normal physiological levels
- 70-80 ng/mL California lifeguard in summer
- 50 ng/mL No D3 secreted in mother's milk; breast cancer risk at 50%
- 38 ng/mL Colon cancer risk reduced by 40%, neuromuscular function impaired
- 32 ng/mL Calcium absorption impaired, bone loss
- 24 ng/mL Average American levels in recent survey; parathyroid hormone suppressed
- 16 ng/mL Necessary to prevent rickets and osteomalacia;
respiratory infections double

1 nmol/L = 2.5 ng/ml

Sun Avoidance/Vitamin D

- Average US wintertime Vitamin D levels (25(OH)D) are below 20 ng/mL
- Average summertime levels are below 30 ng/mL.
- Fewer than 5% at any age have levels above 40 ng/mL
- Fewer than 1% at any age have levels above 50 ng/mL
- Vitamin D experts set optimal levels variously at >40, >50, or >60

Looker AC et al. Vitamin D Status:
United States, 2001-2006 NCHS Data
Brief ■ No. 59 ■ March 2011

Prevention: Micronutrients

- Zinc 9-50% deficient
 - A vitamin up to 30% of children
 - C vitamin 18% severely deficient
 - E vitamin 90% deficient
 - Selenium 50% sub-optimal
-
- Essential fatty acids deficiency common
 - Not heroic, just sufficient to correct deficiencies

Daily Supplement protocol

- Vitamin D 4,000 to 7,000 IU
- Zinc 25 mg (lozenges with exposure)
- Vitamin C 500-1000 mg
- Vitamin E 100-200 IU
- Selenium 200 mcg
- Omega-3 oil 1-3 grams combined EPA + DHA

Vitamin D3 dosing if exposed

- For nearly a century, a dose of 300,000 IU of vitamin D has been given to a child with Rickets, or to Scandinavian adults at the beginning of winter, without harm.
- “If the ability of vitamin D to stimulate the production of virucidal antimicrobial peptides and to suppress cytokine and chemokine production is clinically significant, then pharmacological doses (1000–2000 IU/kg per day for several days) may be useful in the treatment of those viral respiratory infections that peak in wintertime.”
- This translates to 75,000 to 150,000 IU/day for several days in 75 Kg individual.
- Alternately, 50,000 IU/day for 6 days.

Cannell JJ, Vieth R, Umhau JC, Holick MF, Grant WB, Madronich S, Garland CF, Giovannucci E. Epidemic influenza and vitamin D. *Epidemiol Infect.* 2006;134:1129-1140.

Lifestyle factors during prevalence

- Avoid Sleep debt
- Avoid sugar and high glycemic foods.
- Avoid known food allergens
- Garlic in the diet, 1-3 cloves cooked, or raw in appropriate medium
- Exercise to spike body temperature and metabolism
- Sauna, sweat, hot tub
- Smudge, Smudge shower.

Smudging, sweating

- Smudging effectively disinfects air
- Also may disinfect the mucous membranes
- “Smudge shower” Enclosed hot steamy bathroom plus smudge. Rub into all areas of the body, and breathe.
- Hot air from sauna or sweat-lodge may destroy respiratory virus directly, or through stimulation of host response.

Sleep Debt

- 14 young adult male subjects had sleep restricted to 4 hours per night for 6 nights.
- Subjects and a similar control group having 7.5 to 8.5 hours a night sleep, received an influenza immunization after day four of the trial.
- The trial group then rested in bed for 12 hours a night for 7 more days.
- Anti-influenza IgG antibodies at day 14 were only 50% in the sleep deprivation group vs the normal sleep, despite 7 days of deep recovery.

Spiegel, K. (2002). *Effect of Sleep Deprivation on Response to Immunization*. *JAMA*, 288(12), 1471

Prevention: Herbal medicines

During prevalence, when exposure is suspected

- Echinacea frequent dosing
- Boneset effective in 1918 epidemic
- Sambucus anti-influenza specific
- Garlic enhances T_k cell activity
- Astragalus, Codonopsis Take in soups or as tea
- Shiitake mushrooms Cooked in foods, or mushroom extract supplements

Possible formula when exposed

When exposed

Equal parts of:

- Echinacea *Echinacea angustifolia*
- Boneset *Eupatorium perfoliatum*
- Mint *Mentha spp.*
- Osha *Ligusticum porteri*
- Elder (berry or flower) *Sambucus spp.*
- ½ part of Licorice *Glycyrrhiza spp.*
- ½ part of Ginger *Zingiber off.*

Dose: 10-20 drops, 2-3 times a day for prevention

Possible formula when exposed

Equal parts of:

- Echinacea *Echinacea angustifolia*
- Oregon grape (*Mahonia spp.*)
- Western red cedar *Thuja plicata*
- Wild Indigo *Baptisia tinctoria*
- ¼ part Cayenne *Capsicum spp* or Ginger *Zingiber*

Dose: 10-20 drops, 2-3 times a day for prevention.

Therapeutics

Support immunity
Treat fever in stages
Treat dry cough.

Assess for risk of serious disease

- Elders, those with chronic medical conditions, and those on immunosuppressive drugs.
- For COVID-19, 14% of patients develop conditions requiring hospitalization; 6% more require intensive care in hospital
- Although overall mortality in healthy individuals is about 1.4% it is higher in others: patient over 80 y.o. 21.9%; with CVD 13.2%, with Diabetes, 9%, with Hypertension, 8.4%, with Chronic Respiratory Disease 8%, with Cancer, 7.6%
- Establish close monitoring for severe disease, with contingencies for hospital care.

Historical view of fever

- Hippocratic corpus
- Thomsonian/Physiomedicalist
- Nature Cure
- Allopathic from Galen to the present

In the older literature of natural medicine, the discussion of fever and inflammation defines the school as vitalist/natural vs allopathic

Fever

- A **beneficial** rise in the body metabolism and temperature.
- The thermogenic set point is raised.
- Increased manufacture of antibodies and white blood cells -- Antibody production is increased about 20-fold.
- Retards growth and reproduction of bacteria and virus
- Aids body's acute phase reaction
- Increased circulation to surface defenses
- Increased elimination.

Recent review of pediatric fever

- “Fever . . . is not the primary illness but is a physiologic mechanism that has beneficial effects in fighting infection.”
- “There is no evidence that fever itself worsens the course of an illness or that it causes long-term neurologic complications.”
- “The primary goal of treating the febrile child should be to *improve the child's overall comfort* rather than focus on the normalization of body temperature.”
- “. . . monitoring activity, observing for signs of serious illness, encouraging appropriate fluid intake . . .” are appropriate measures.

Sullivan JE, Farrar HC. Fever and antipyretic use in children. Section on Clinical Pharmacology and Therapeutics; Committee on Drugs *Pediatrics*. 2011 Mar;127(3):580-7.

“Studies of health care workers, including physicians, have revealed that most believe that the risk of heat-related adverse outcomes is increased with temperatures above 40° C (104° F), *although this belief is not justified.*”

Fever is not hyperthermia

- *Hyperthermia* (heat stroke) has no elevation of set point, but is a failure of compensatory mechanisms, at temperatures from 105.8 to 107.6 damage from hyperthermia occurs
- *Fever* has elevated set point with compensatory cooling mechanisms.
- “For practical purposes except in rare instances, the human oral temperature cannot rise above 106 degrees” *Harrison’s Internal Medicine*
- *Hyperpyrexia* fever above 106 degrees F. “08% of pediatric emergency center admissions) do not require any more special evaluation by the physician than any febrile child with a temperature below 106.” No more likely to indicate bacterial than viral infection.

Risks of fever

- While fever itself is not pathological, it may be the sign of infectious or non-infectious pathologies that may be serious.
- The chief concern for higher fevers is **dehydration** or **metabolic exhaustion** in elderly or debilitated patients.
High fever in cardiac patients may destabilize arterial plaques or cause stroke in patients with cerebral arterial disease.

Normal temperature

- The supposed average of 98.6 was based on inaccurate data. *
- Meta-analysis of measurements in healthy subject from 1935 to 1999, showed a median normal oral temperature of 97.7 **
- Typical fluctuation during the day of 0.9 degrees F, from 6AM to 4PM peak.
- Average among elders is 96.8 with a reduced diurnal rise of .5 degrees

*Mackowiak PA, Wasserman SS, Levine MM. A critical appraisal of 98.6 degrees F, the upper limit of the normal body temperature, and other legacies of Carl Reinhold August Wunderlich. *JAMA* 1992;268:1578-1580.

**Sund-Levander M, Forsberg C, Wahren LK. Normal oral, rectal, tympanic and axillary body temperature in adult men and women: a systematic literature review. *Scand J Caring Sci*. 2002 Jun;16(2):122-8. Review.

Range of normal temperatures

- Oral 91.8 - 100.8 (Male 96.3 - 99.9)
- Rectal 94 - 100
- Tympanic 95.7 - 100
- Axial 95.9 - 100.4

Sund-Levander M, Forsberg C, Wahren LK. Normal oral, rectal, tympanic and axillary body temperature in adult men and women: a systematic literature review. *Scand J Caring Sci*. 2002 Jun;16(2):122-8. Review.

Fever range

- Range 98.9 at 6AM to 99.9 At 6PM are the upper range of normal in healthy adults under age 40.
- Lower limits should be considered in elders, for example 98.0 AM to 98.5 PM may indicate a febrile response in an elder.

- 98 - 99 degrees. Influenza virus dies.
- 99.5 The digestive system shuts down.
- 104 degrees. Gonococcus is killed. Polio virus replication is reduced by a factor of 250. Normal temperature may reach 104 degrees under vigorous exercise.
- 106 degrees. Pneumococcus dies. Some spirochetes die. (Malaria traditionally induced to fight syphilis)
- 106-110 malignant cells are selectively killed
- 108 brain damage may occur due to denaturation of proteins.
- 110 Human cells begin to die.

Coronavirus and body temperature

- A clinical report from Hong Kong suggested in 2003 that SARS coronavirus is sensitive to human body temperature.
- “If the body temperature is below 96.8F it grows very rapidly.”
- “If the body temperature is above 98.6F the virus is attenuated or killed. Milder inflammatory response and recovery.”
- “Patients with high fever can kill the virus”
- The author suggests increasing body temperature through environment or exercise may be of benefit.

Antipyretic therapy

Aspirin and NSAID may promote infection

- Animal trials: Rabbits infected with *Pasteurella* had a 29% mortality rate. One group had their fever lowered by 1.5 degrees with salicylates, and had 100% mortality. Salicylates alone in uninfected rabbits caused no mortality. Treated rabbits had a lower white blood cell count than their infected but untreated counterparts, and their lung and liver bacterial counts were higher.

Vaughn LK, Veale WL, Cooper KE. Effects of antipyresis on bacterial numbers in infected rabbits. *Brain Res Bull*. 1981 Aug;7(2):175-80.

Vaughn LK, Veale WL, Cooper KE. Antipyresis: its effect on mortality rate of bacterially infected rabbits. *Brain Res Bull*. 1980 Jan-Feb;5(1):69-73.

Influenza mortality increased

- Animal trials: on meta-analysis of 8 trials, the use of aspirin, acetaminophen, or diclofenac increased mortality from experimental influenza infection by 34%.

Eyers S, Weatherall M, Shirtcliffe P, Perrin K, Beasley R. The effect on mortality of antipyretics in the treatment of influenza infection: systematic review and meta-analysis. *J R Soc Med.* 2010 Oct;103(10):403-11.

Pneumonia mortality

- Animal trials: In a meta-analysis of 3 studies, antipyretic therapy in pneumonia doubled mortality rate in animals. The *Pneumococcus* bacterium is temperature sensitive.

Jefferies S, Weatherall M, Young P, Evers S, Beasley R. Systematic review and meta-analysis of the effects of antipyretic medications on mortality in *Streptococcus pneumoniae* infections. *Postgrad Med J*. 2012 Jan;88(1035):21-7.

NSAID and interferon response

- NSAID inhibit cyclo-oxygenase, which is essential for the production of the interferon response to viral infection, the primary defense against infection.

Pottathil R, Chandrabose KA, Cuatrecasas P, Lang DJ. Establishment of the interferon-mediated antiviral state: role of fatty acid cyclooxygenase. Proc Natl Acad Sci U S A. 1980 Sep;77(9):5437-40.

Antibody response in humans

- Human trials of experimental rhinovirus infection treated with salicylates and NSAID. Lowering the fever with aspirin and acetaminophen suppressed antibody response and increased the severity of subjective symptoms. Ibuprofen had a strong similar trend (worse than placebo on every measure) but which did not reach statistical significance.

Graham NM1, Burrell CJ, Douglas RM, Debelle P, Davies L. Adverse effects of aspirin, acetaminophen, and ibuprofen on immune function, viral shedding, and clinical status in rhinovirus-infected volunteers. *J Infect Dis.* 1990 Dec;162(6):1277-82.

Duration of illness

- Patients with experimental infection with *Influenza* or *Shigella* were given aspirin or acetaminophen.
- “There was a striking correlation between antipyretic therapy and duration of illness in subjects infected with influenza A and *Shigella sonnei*”

Plaisance KI, Kudaravalli S, Wasserman SS, Levine MM, Mackowiak PA. Effect of antipyretic therapy on the duration of illness in experimental *influenza A*, *Shigella sonnei*, and *Rickettsia rickettsii* infections. *Pharmacotherapy*. 2000 Dec;20(12):1417-22.

Aspirin in the 1918 influenza pandemic

- May have been responsible for a large proportion of excess mortality in the U.S.
- Standard medical regimen in civilian and military population was 8.0-31.2 g per day, levels which today are known to be frankly toxic
- This dose would result in an expected 33% of subjects developing hyperventilation and 3% pulmonary edema.
- Mortality rate in the U.S. from the pandemic was about 3%.
- Antipyretic *suppression of antiviral mechanisms*, in addition to adverse effects of *toxicity*, contributed to the severity of the pandemic.

Starko KM. Salicylates and pandemic influenza mortality, 1918-1919 pharmacology, pathology, and historic evidence. *Clin Infect Dis*. 2009 Nov 1;49(9):1405-10.

Ill effects of chronic suppression

- “Post viral syndrome”
- Collapse of vital structures
- Chronic fatigue
- “Lake Tahoe syndrome” and chronic fatigue.

Stages of fever

1. Set point elevated, cold and chills predominate
2. Set point peak, elevated pulse and temperature
3. Fluctuating set-point, cycling fever, sweating, and chills
4. Crisis and set point drop, sweating
5. Recuperation

First stage: Set point rising

- Because the body temperature is now below the set point, the subjective feeling is cold. Skin cold. Symptoms resemble hypothermia.
- Normal range actual body temperature, rising
- Feeling of cold, aversion to cold and wind.
- Shivering raises the metabolism and generates heat.
- Paleness. Closing of the pores to prevent sweating and heat loss.

Therapeutics

- Complete rest.
- *Immediate fast.*
- Long warm to hot shower or bath.
- Rest in bed with covers.
- Hydrate. Hot drinks and teas.
- Stimulating (hot) diaphoretics.
- Capsicum 500 mg. Cinnamon 5-10g. Fresh Ginger 3-10g. Osha 3-10g Garlic, onion, scallions 3-10g.

Thomson's Composition Powder

Core formula

- Myrica Bayberry 8 parts
- Zingiber Ginger 8 parts
- Populus Poplar bark 8 parts
- Capsicum Cayenne 1 part
- Eugenia Cloves 1 part

- With or Abies, Quercus instead of Populus in some published versions.

Fasting and Ghrelin

- Secreted by the gut wall of the stomach, small intestine, and large intestine when empty
- Has systemic anti-inflammatory effects
- May act as selective Cox-2 inhibitor
- Has febrifuge effects
- Promotes autophagy in the system and locally in the gut
- **One basis for traditional aphorisms to fast during fever, and for traditions or herbal emesis and catharsis in febrile illness.**

Second Stage: Peak fever

- Normally 102-104. “A good working fever.”
- Optimizes antibody production.
- The skin hot and dry.
- Patient may not feel hot.
- Pulse fast.
- Patient is drowsy.
- Muscles ache due to elevated cytokines. Tissue of long muscles is broken down to make amino acids available for immune component manufacture and tissue repair.
- Gut motility decreases and the natural appetite disappears.
- Blood concentrations of iron and zinc are reduced (denying food to pathogens).

Therapeutics

- Rest, well ventilated room, but no draft. Continue fast until fever falls below 99 degrees.
- Emphasize physical and mental comfort of patient.
- Avoid sour flavors and astringents.
- Melissa water.
- Tepid or cool water and drinks.
- Cooling and relaxant diaphoretics
- *Mentha*; *Mentha/Achillea*
- *Eupatorium*, *Sambucus*, *Verbena*.
- Sedative relaxants; *Scutellaria* tea, *Pedicularis*.

Third stage: Intermittent fluctuations

- Diurnal fluctuations 6AM to 6PM.
- Diurnal fluctuations with cytokine waves.
- Day to day fluctuations over time with cytokine storms.
- Alternating cycles of fever, sweating, and chills.
- May develop food cravings, often for harmful foods.

Therapeutics

- Continue strategies already in place.
- Use moderate diaphoretics in formulas with mixed stimulant and relaxant effects.
- Keep patient warm when chilled.
- Intermittent short hot showers followed by warm blankets.
- Do not get out of bed too soon.
- See historical formulas with mixed herbal actions in following section.

Caution on diaphoretics

- Overdose, prolonged use, or inappropriate use may deplete the vitality and promote dehydration
- Caution in depleted or already dehydrated patients.
- Avoid driving excessive perspiration
- The purpose is to encourage *ventilation* not perspiration.
- “Only until normal moisture of the skin is attained”
 - William Cook - Physiomedicalist
- “Intake of these herbs should be discontinued immediately when the desired therapeutic results are attained”
 - Chen and Chen. Classical Chinese.
 -

Avoid herbal antipyretic strategy

- Bitter ‘heat-clearing’ herbs may reduce fever/heat.
- It is as much a therapeutic error to use strong bitter herbs to reduce the heat of fever as it is with antipyretic drugs.
- Berberine containing herbs, while useful in general for “hot” and infectious conditions, are generally inappropriate during the febrile stage of a disease.
- “Not until the fever has passed” Homeopath and Eclectic Edwin Hale on *Hydrastis*.

Fourth stage: Crisis and fall

- The set point falls.
- Drop may be abrupt, gradual, or in stages
- Feelings of heat
- Sweating may “soak the sheets.”

Therapeutics

- “If it ain’t broke don’t fix it.”
- Rest
- Hydrate
- Avoid chill
- Support elevated body temperature
- Do not get out of bed too soon

Its not over till its over

- Influenza specifically has a seven day cycle.
- The fever may pass and the condition appear to be resolved after 2-3 day.
- See previous, cytokine surges recur again on day 4-6.
- 1918 retrospective study at Johns Hopkins: “Those who went to bed the earliest, stayed the longest, and had the best nursing care were most likely to survive.”
- The normal cycle is not well defined in COVID-19, but in complications, may last for 2-3 weeks.

Fifth stage: Recuperation

- Weakness, weak pulse
- Fast thready pulse
- Light headedness, dizziness
- Thirst.
- Possible alternating feelings of hot and cold.
-

Therapeutics

- Wait for natural hunger to return.
- Rest. Do not go back to work too soon.
- Demulcent foods and drinks. Fruit. Soups. Easily digestible stews. Seaweeds.
- Replenish omega-3 fatty acids.
- Althea water. *Althea* 3 with *Ulmus* 1 and *Glycyrrhiza* 1
- *Asparagus* (shatavari) and *Lycium* tea.
- Mild bitter tonics sparingly. *Populus* or *Salix*.
- This stage at least the length or double the length of the actual fever, possibly longer

Materia medica categories

Strong heating diaphoretics

- Capsicum
- Eugenia
- Cinnamomum (cassia)
- Zingiber (fresh)
- Asarum
- Zanthoxylum

Milder stimulating diaphoretics

- Ligusticum (osha)
- Achillea (as hot tea)
- Monarda

Mixed stimulating and relaxing

- *Mentha arvensis*
- *Mentha piperita*
- *Mentha spicata*
- *Melissa*
- *Nepeta*

Relaxant diaphoretics

- *Eupatorium*, warm tea
- *Sambucus*
- *Verbena spp.*
- *Asclepias tuberosa*
- *Lobelia*
- *Dioscorea villosa*
- *Corallorhiza spp*

Classic formulas

Generally combine mild stimulation with relaxation or sedation

Classical combinations

- Many traditional formulas contain combinations of *Mentha*, *Achillea*, and *Sambucus*
- Two mixed diaphoretics and one relaxant

- *Mentha* and *Sambucus*
- mild stimulant, mild relaxant

Edward Shook - Physiomedicalist

- *Mentha* and *Achillea*
- Mild mixed stimulant/relexant

Herbert Nowell - Physiomedicalist and Naturopath

- *Eupatorium* 1
- *Asclepias* 2
- *Scutellaria* 1
 - pure relaxant plus a sedative
- To the above, 1 part *Capsicum* if chills are predominant stimulant

R Swinburne Clymer - Physiomedicalist

- *Zingiber and Nepeta*
- Stimulant with modification for children

Priest and Priest - Physiomedicalist

- Thymus, Nepeta, Eupatorium
- stimulant, mixed, neutral

Tommye Bass - Appalachian

- *Zingiber* and *Lobelia*
- Stimulant and relaxant

Wm Cook - Physiomedicalist

Some individual herbs

Select those herbs which increase patient comfort and also enhance immunity and or mildly reduce inflammation, something which antipyretic drugs can never achieve.

General considerations

- Administer diaphoretics as hot teas.
- If using the tincture, deliver in hot water.
- Many diaphoretics have a hot/cold polarity - diaphoretic when given hot in mild concentration, but alterative/diuretic when given cold in strong concentration.
- Many warming diaphoretics are also emmenagogue.
- Many warming diaphoretics are also carminative and benefit the digestion.

Eupatorium perfoliatum (Boneset)

- The most famous and extensively used diaphoretic/febrifuge in North American history.
- Learned from Native Americans by European Colonists
- Became the panacea herbs for febrile illness in the colonies and through the mid-19th century.
- Used for malaria, dengue fever, yellow fever, influenza, and garden-variety fevers. Improved survival in influenza epidemics.
- Clinical effects imply that it enhances immunity and reduces cytokine storm.
- Consider the tea may be much more effective than tincture. (See research on polysaccharides).
- Potentially emetic.
- Very bitter flavor, combines well with Zingiber for flavor and effect.
- Due to potential hepatotoxicity, this herb should not be taken in pregnancy, lactation, or in young children, or for more than 2 weeks in an adult.

Boneset

- With Scutellaria, as decoction, and something warming.
- With Asclepias. This is very relaxant, very pain relieving.
- With zingiber
- With other relaxant diaphoretics
- For comfort with Actaea and Caulophyllum
- Lavandula
- Mentha
- Due to potential hepatotoxicity, this herb should not be taken in pregnancy, lactation, or in young children, or for more than 2 weeks in an adult.

Sambucus species

- Berries or flowers used. Traditional indications are equivalent.
- Recent research shows that a syrup shortens the duration and severity of the fever of influenza. For most patients, the fever is gone by the end of the second day.
- May have direct activity against influenza virus (speculative).
- Traditional indication indicate that it enhances antiviral defenses in the body.

Achillea

- Diaphoretic in hot delivery media
- More tonic, astringent, and diuretic in cold media.
- Aromatic bitter, warming through effects of essential oils, cooling through bitter principles
- Combines well with *Mentha* to enhance diaphoresis.

Mentha species

- *Mentha arvensis* (corn mint, poleo mint), most stimulating, contains the most menthol.
- *Mentha piperita*, intermediate stimulation, mid range menthol
- *Mentha spicata*, least stimulation, lowest menthol

Asclepias tuberosa

- “pure relaxant”
- Relaxes pores, allows you to “sweat for free”
- Affects mucous, serous, and synovial membranes, cooling inflammation, and facilitating normal secretions.
- Combines well with a little *Zingiber*

Lobelia inflata

- A non-toxic plant. See series of articles at <http://medherb.com>
- A powerful relaxant to both smooth and skeletal muscle
- A relaxant diaphoretic
- A strong relaxant expectorant
- Relaxes the cough reflex
- Emetic and/or cathartic in higher doses.
- Combines well with a small amount of Capsicum or a somewhat larger amount of Zingiber.

Treatment of dry cough

Dry Cough

- Cough may have copious mucous, stuck mucous, or dry. Distinguish between stuck and dry coughs.
- Common presenting symptom of influenza is the dry irritable cough disturbing sleep.
- The natural host cell of the influenza virus is the epithelial cell in the bronchial tract and trachea. The infected cells are inflamed by the body's attempt to remove them, and mucous secretions may be deficient.
- Many herbal *stimulant expectorants* that are useful in moist coughs with accumulated or stuck mucous work by irritating the tissues slightly to produce new mucous.
- These usually are aggravating in a true dry inflamed cough
- The two categories most useful for the acute dry irritable cough are *relaxant expectorants* and *demulcents*.

Relaxant expectorants

- *Tussilago farfara*. Mixed relaxant and expectorant properties
- *Lobelia inflata*. Non-toxic, use lower doses.
- *Asclepias tuberosa*. Benefits mucous and serous membranes
- *Usnea* species. Water extract
- *Sticta pulmonaria*. Lungwort
- *Thymus vulgaris*. Mixed relaxation and stimulation, antispasmodic

Demulcents for cough

- *Althaea off, rosea*. Pure relaxant and demulcent. As effective as hydrocodone in one trial.
- *Tussilago farfara*. As above.
- *Ulmus fulva*, and other *Ulmus* species.
- *Glycyrrhiza*. Effective demulcent and moistener can counteract irritating effects of the milder stimulant expectorants in formulas. Taken in excess as tea or powder, may increase force of a cough through tonifying effects.

Media: Honey and sugar

- William Cook, M.D: Demulcent, and at the same time moderately stimulant to the respiratory mucous membranes.
- These are common components of cough syrups, and because of their gentle expectorant action, many cough preparations can be given in syrup form
- A hydromel is a simple combination of honey and water, such as would be used to ferment mead.

Vinegar, Lemon, Lime

- William Cook, M.D. Promotes the secretions of the throat and respiratory tract membranes
- Cook states that the action of vinegar tinctures are mostly restricted to the respiratory passages and stomach.
- An oxymel is a combination of vinegar and honey.

Recipe: Basic onion syrup

- Chop 5 or 6 white onions and place them in a double boiler.
- Add ½ cup of honey and the juice of 1 lemon and cook on lowest heat possible for several hours.
- Strain the mixture and take by the tablespoon from every ½ hour to every few hours as needed.
- May be used as delivery medium for tinctures.

Stimulating expectorants

- Avoid as simples in cough of influenza. May be used as smaller part of a net demulcent, relaxant formula
- Garlic
- *Aralia racemosa*
- *Inula helenium*
- *Marrubium vulgare*
- *Grindelia* spp
- *Ligusticum* spp.

Verbascum

- Leaf has complex effects
- Can be stimulating and irritating especially to dry cough
- Also has relaxant effects
- Frequently listed as demulcent in books, but this probably refers to flowers.
- Flowers are demulcent and relaxant, cooling, antiinflammatory

Simple Dry cough formula

- Althaea hydromel, add strong honey to Althaea tea.
- Add 10 drops of lobelia tincture per 6 ounce cup of tea.
- Dose per 2 hours.

Dry cough syrup

- Simmer 4 oz fresh Zingiber (ginger) root and 2 oz Glycyrrhiza (licorice) in 4 pints of water over low heat until the mixture has been reduced to 3 pints.
- Strain and add 3 cups of honey and the juice of one lemon.
- Add 1 cup each of Lobelia vinegar and Asclepias tincture
- Skim any froth that forms
- Add 1 dram each of essential oils of thyme and anise.
- Adults one Tbls, children 1 tsp, 5-6 times per day

Jillian Stansbury ND

Tea based oxymel

- Place one ounce of an herb in one quart of water.
- Reduce to a pint and a half.
- Strain.
- Add 4 ounces of vinegar and 4 ounces of honey.

Tincture based oxymel

- 1 pint of apple cider vinegar
- 2 ¼ lbs of honey
- Combine in a pot and simmer to the consistency of syrup.

Keep as pre-mixed medium for cough tinctures.

Tinctures can be delivered in a ratio of one part of tincture to 3 parts of oxymel.
